A quick look at retrievals over Brazil

Christopher Barnet, UMBC/JCET

Roberto V. Calheiros, Agencia Espacial Brasileira(AEB)

Rodrigo Augusto Ferreira de Souza,  
Instituto Nacional Pesquisas Espaciais (INPE)

# The Basic Retrieval Equation

For discussion, assume a retrieval equation looks like

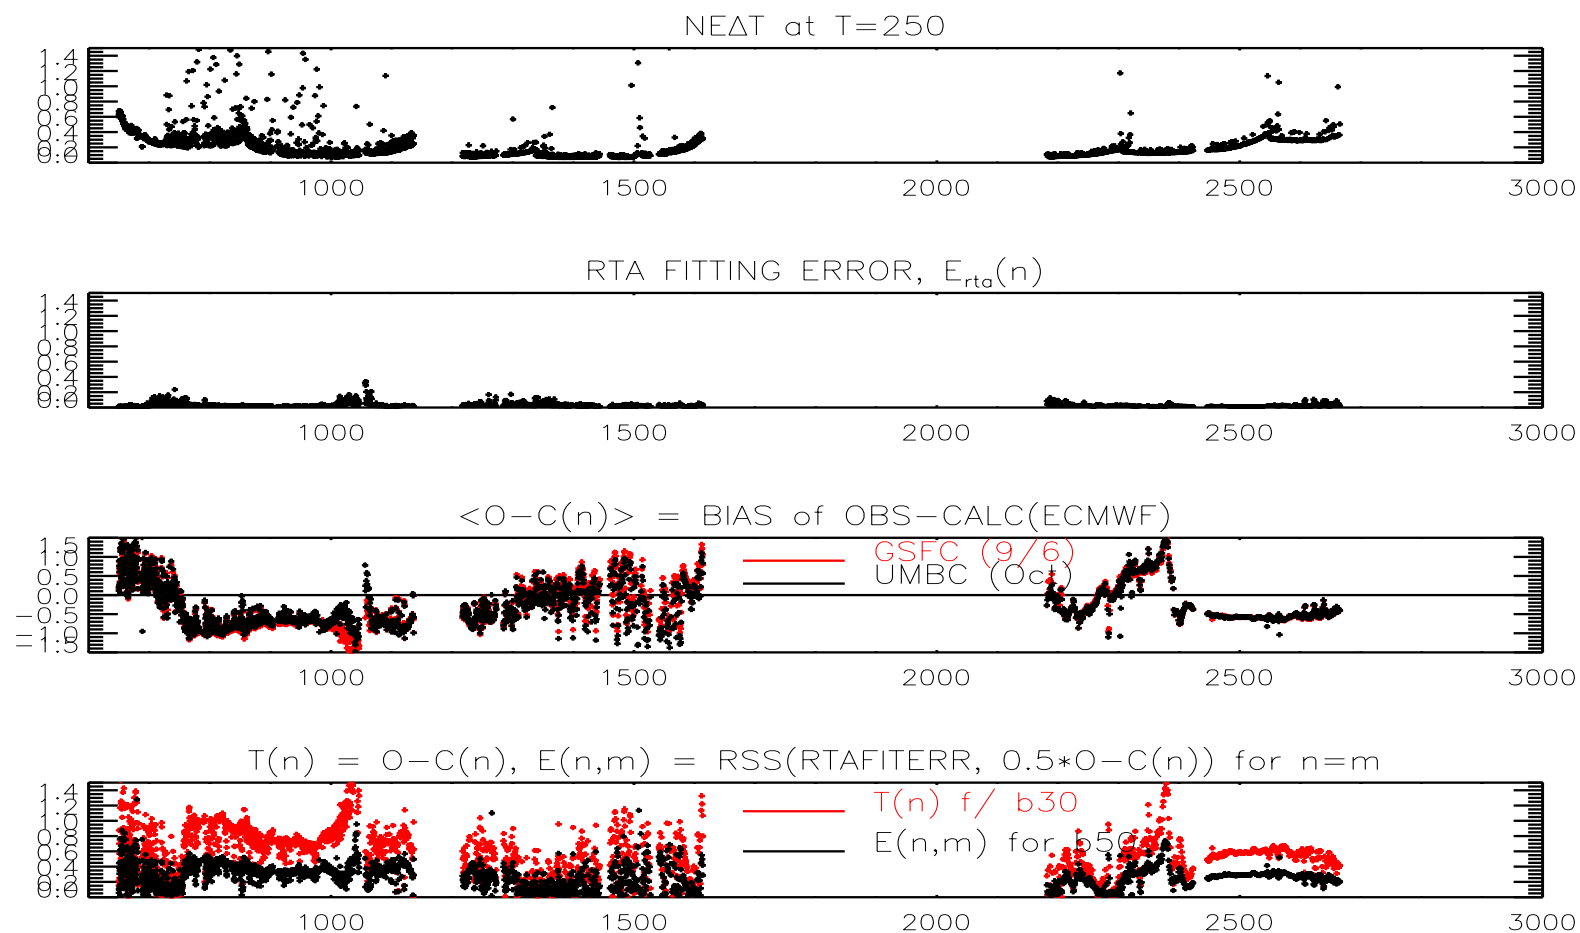

$$\Delta X_i = [S'_{i,n} \cdot W_{n,m} \cdot S_{m,j} + H_{i,j}]^{-1} \cdot S'_{j,m} \cdot W_{m,n} \cdot (O - C(n) + T(n)) \quad (1.1)$$

where,  $n$  and  $m$  are channel indices,  $S_{n,i}$  is the sensitivity of channel  $n$  to parameter  $i$  (or  $j$ ),  $O - C(n)$  is the observed radiances minus the radiances computed from the current state of  $X$ .  $T(n)$  is radiance tuning, if applied.

The weighting matrix,  $W_{n,m}$  is derived from the covariance of instrument and geophysical errors,  $N_{n,m}$  that are a strong function of cloudiness due to the linear combinations imposed by cloud clearing. In addition, we could have other error sources, such as RTA and spectroscopy errors,  $E_{n,m}$ .

$$W_{n,m} = [N_{n,m} + E_{n,m}]^{-1} \quad (1.2)$$

# Biases of O-C

BIASES of O-C were determined by comparison of AIRS with ECMWF computed radiances for CLEAR, OCEAN, NIGHT conditions. Infrared appears to be stable in Sep. and Oct.

## Tuning versus Error Terms

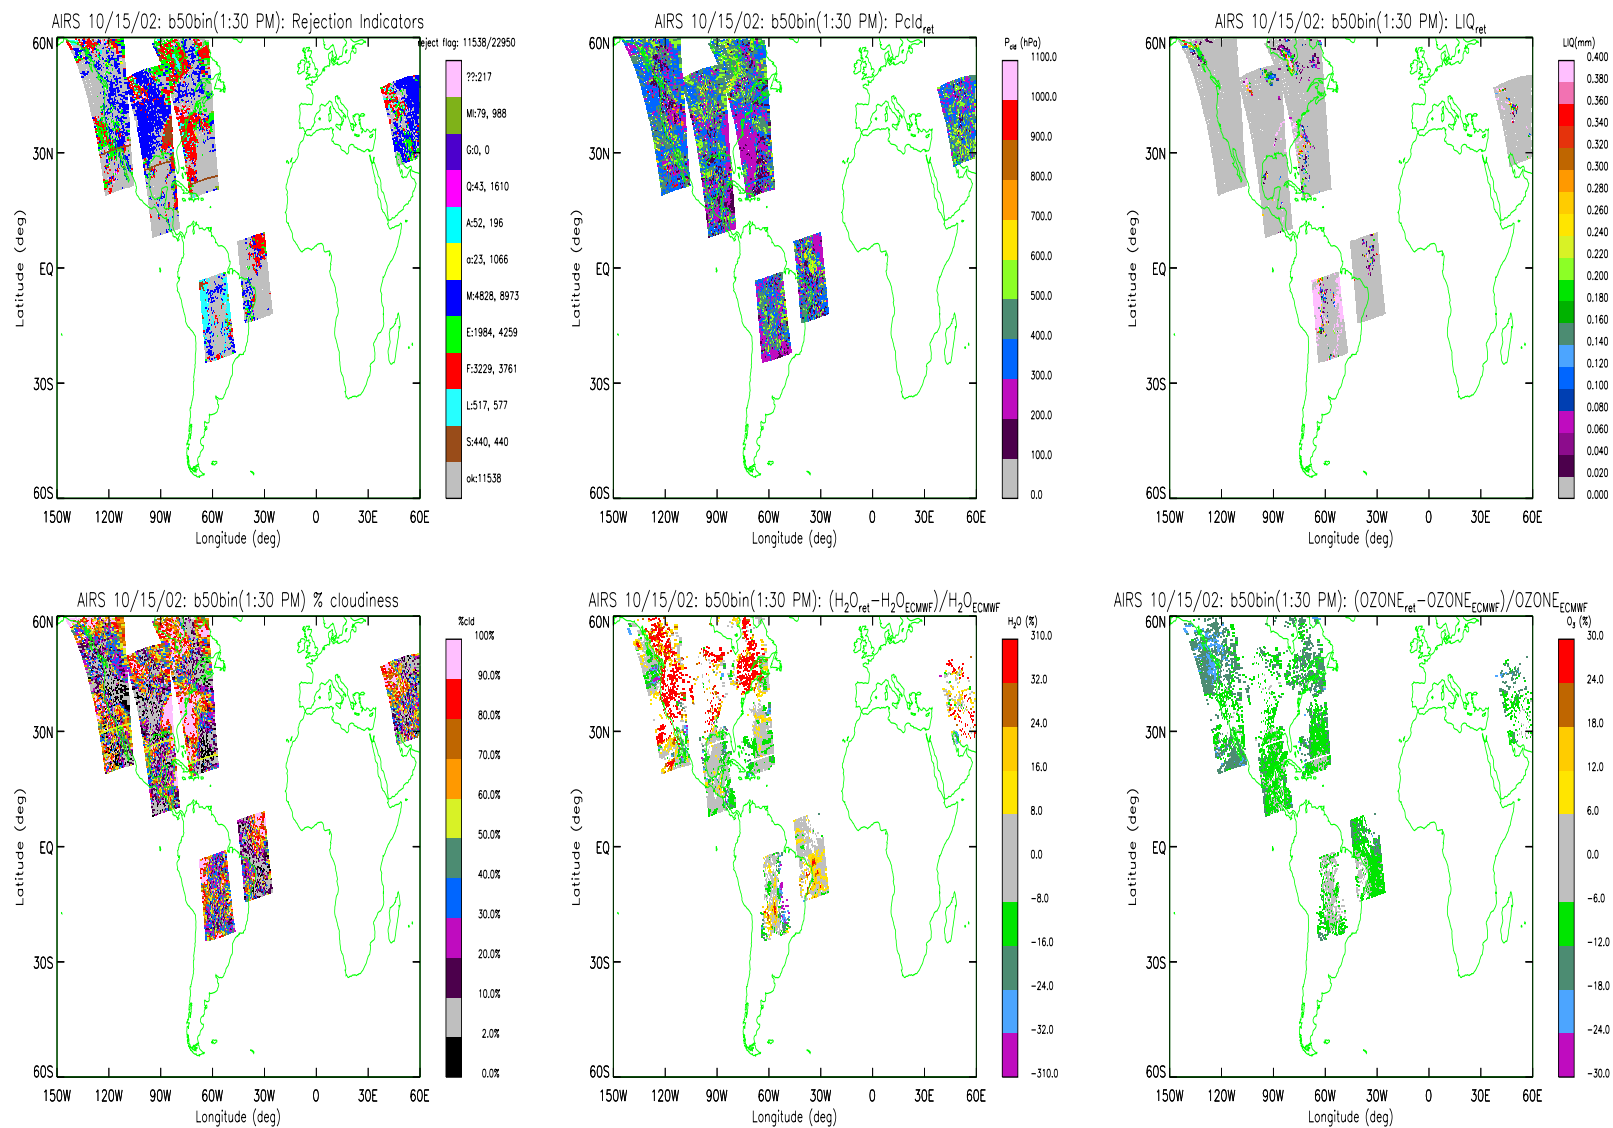

- If  $E(n, m) = 0$  then we believe  $O - C(n) - T(n)$  which means the retrieval assumes very low errors
- If  $E(n, m) \neq 0$  then
  - $O - C(n)$  is not believed entirely
  - AMSU & AIRS convergence is relaxed  $\Rightarrow$  greater yield.
- Experiments with INFRARED TUNING set to  $\overline{O - C(n)}$  and experiments with the error term set to  $\overline{O - C(n)}$  have similar results – when this is the only change applied!
- Since biases on obs-calc's,  $\overline{O - C(n)}$  has both forecast errors and spectroscopy/instrument errors we attempted an experiment with only the diagonal error term specified

$$E_{n,n} = \left( \frac{\overline{O - C(n)}}{2} \right)^2 + E_{rta}(n)^2 \quad (1.3)$$

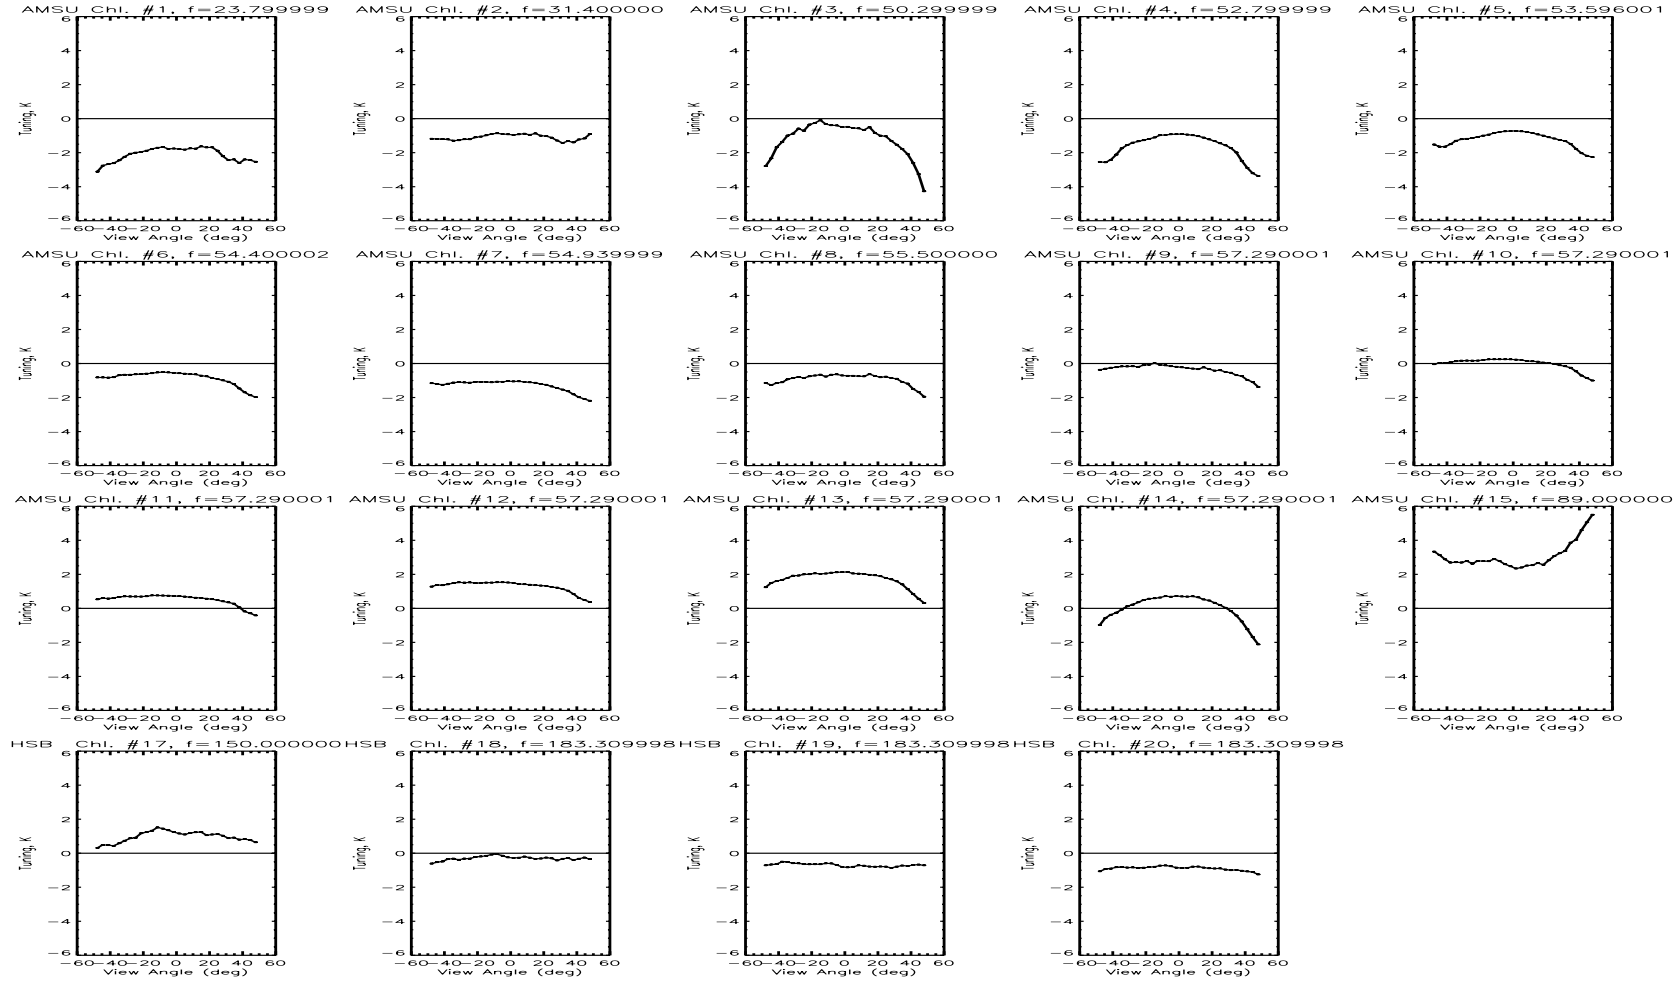

## Conclusions about INFRARED tuning

- All experiments done to date used a simple BIAS tuning for the microwave.
- We recently fixed two BUGs with the MICROWAVE tuning in which we inadvertantly set HSB tuning equal to AMSU's tuning with the opposite sign  $T(\text{HSB}) = -T(\text{AMSU}) \Rightarrow$  Statistics of 70 granules within  $\pm 60^\circ$  latitude on 9/6/02 with and without this BUG are VERY similar.
- While global and statistical views have value, it is also IMPERATIVE that we look at individual & independent validation cases to determine issues w/ regard to tuning.
- I ran  $\approx 2500$  granules with  $T(n) = 0$  and  $E(n, m)$  specified by Eqn. 1.3 from 8/31/02 to 11/30/02 to look for trends and provide retrievals at validation sites in the US and Brazil.
- Tomorrow these retrieval results will be compared to coordinated in-situ during  $\approx 90$  AQUA overpasses

# Oct. 15, 2002: 1:30 p.m.

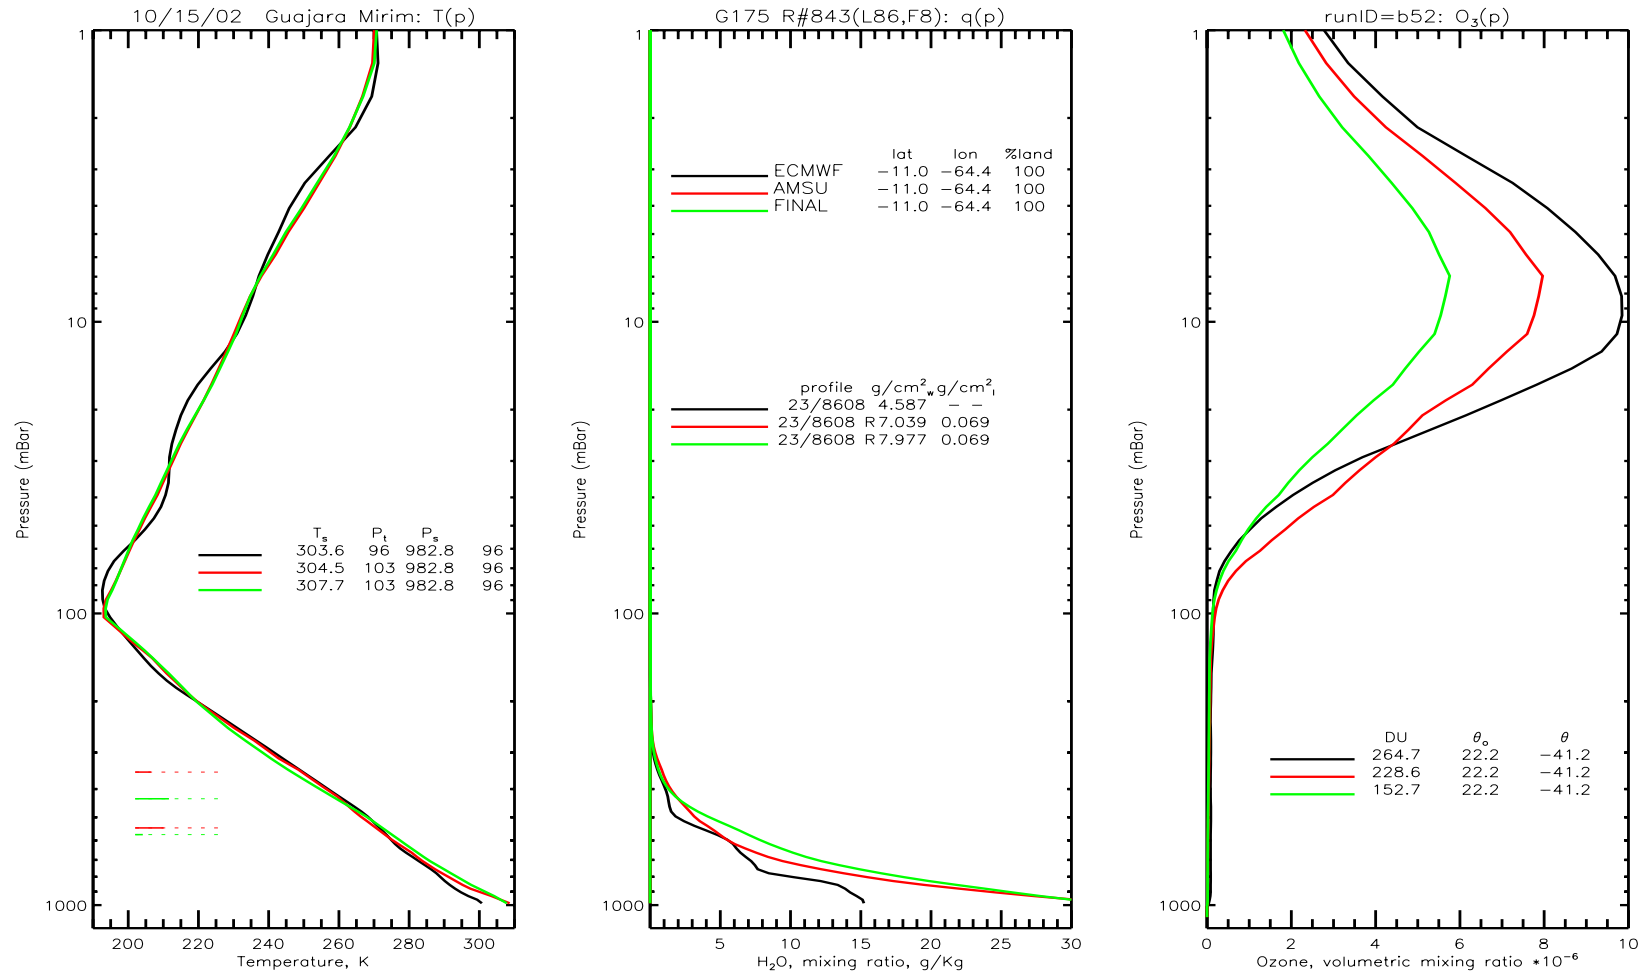

# Microwave Tuning

Microwave tuning determined from  $\approx 45,000$  cases from Sep. 6, 2002. Cases were restricted to  $\pm 60$  latitude, OCEAN, and NO Liquid water.

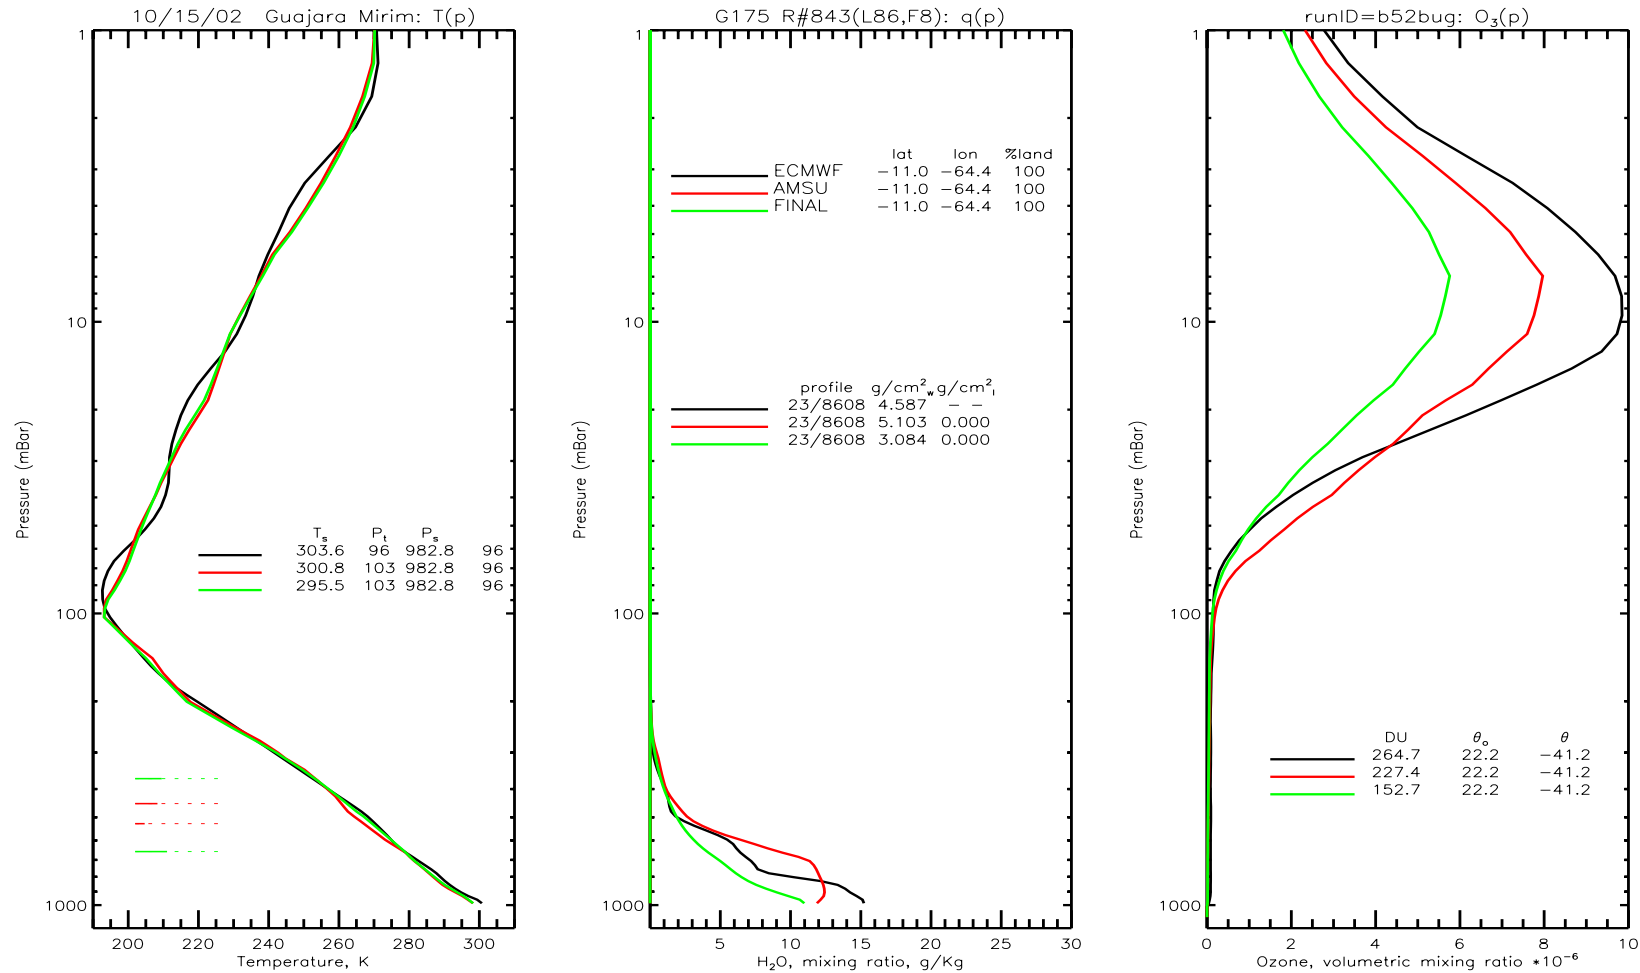

# Guajara Mirim, Oct. 15, 2003

Baseline run (“b50” w/ HSB T(n) BUGS fixed) using T(n)=0, E(n,n) is set as in Eqn. 1.3.

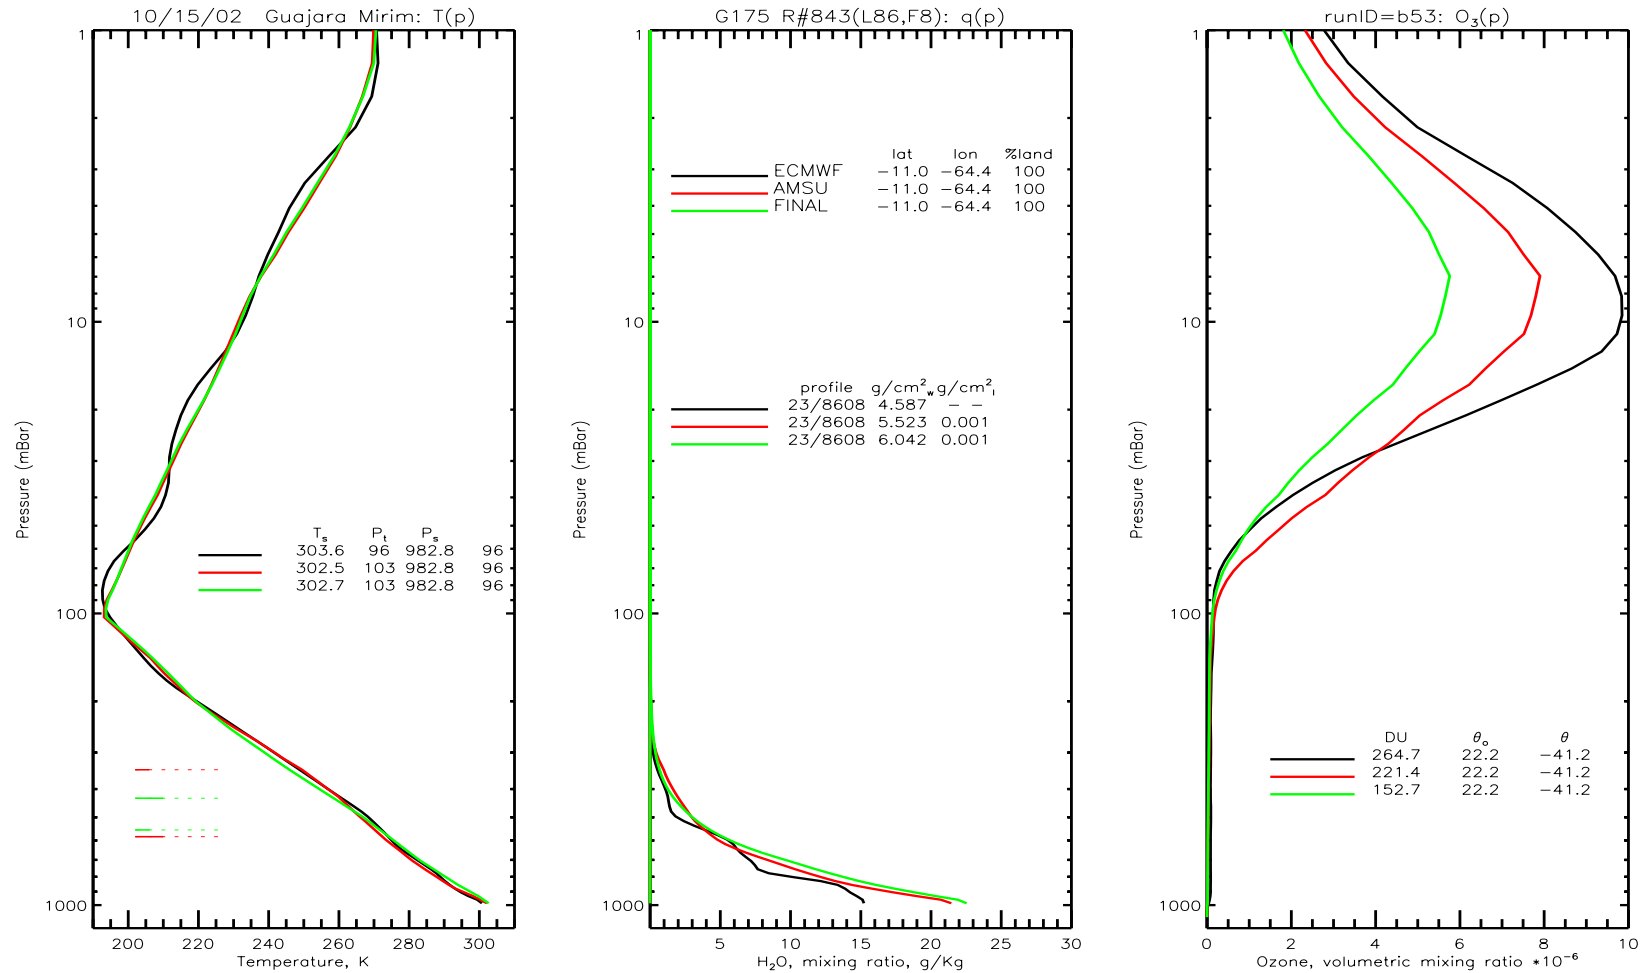

NOTE: problem w/ q(p) and large L(p). Also, q(p) never exceeds saturation

# Guajara Mirim, Oct. 15, 2003

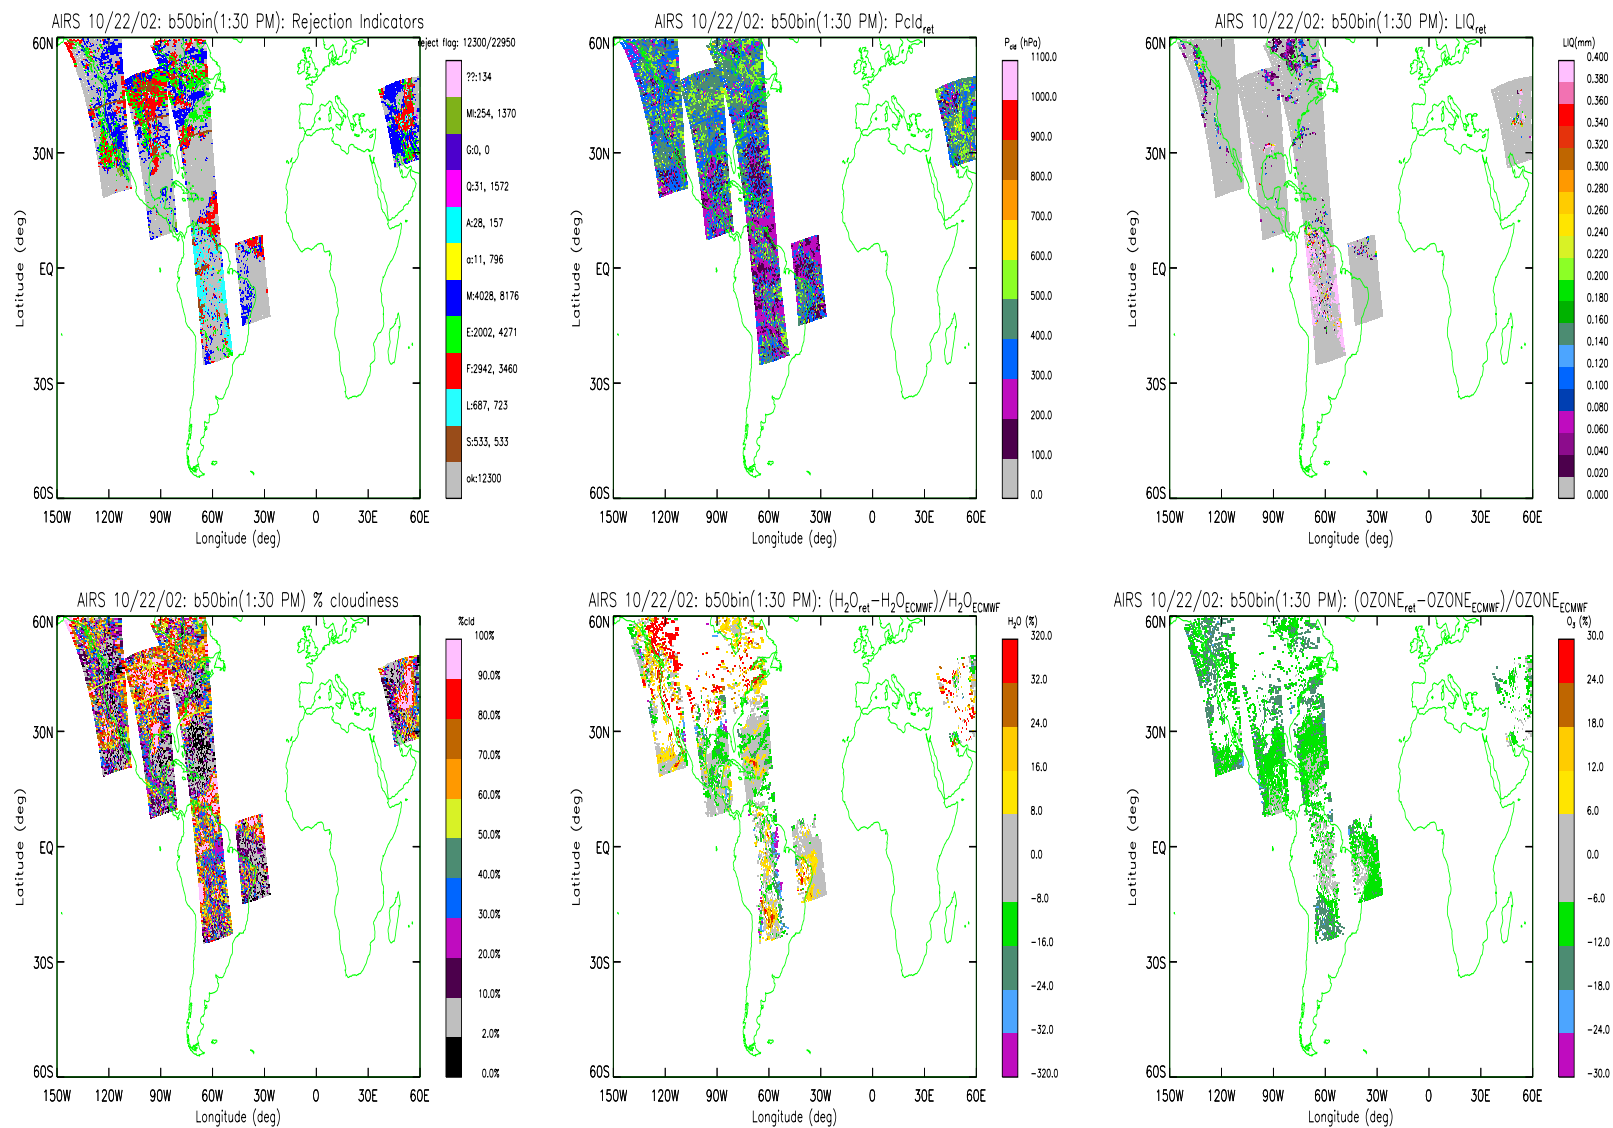

Baseline run w/ HSB T(n) BUGS re-installed. NOTE that L(p) is zero here. This emulates a “b30” system w/o TUNING

# Guajara Mirim, Oct. 15, 2003

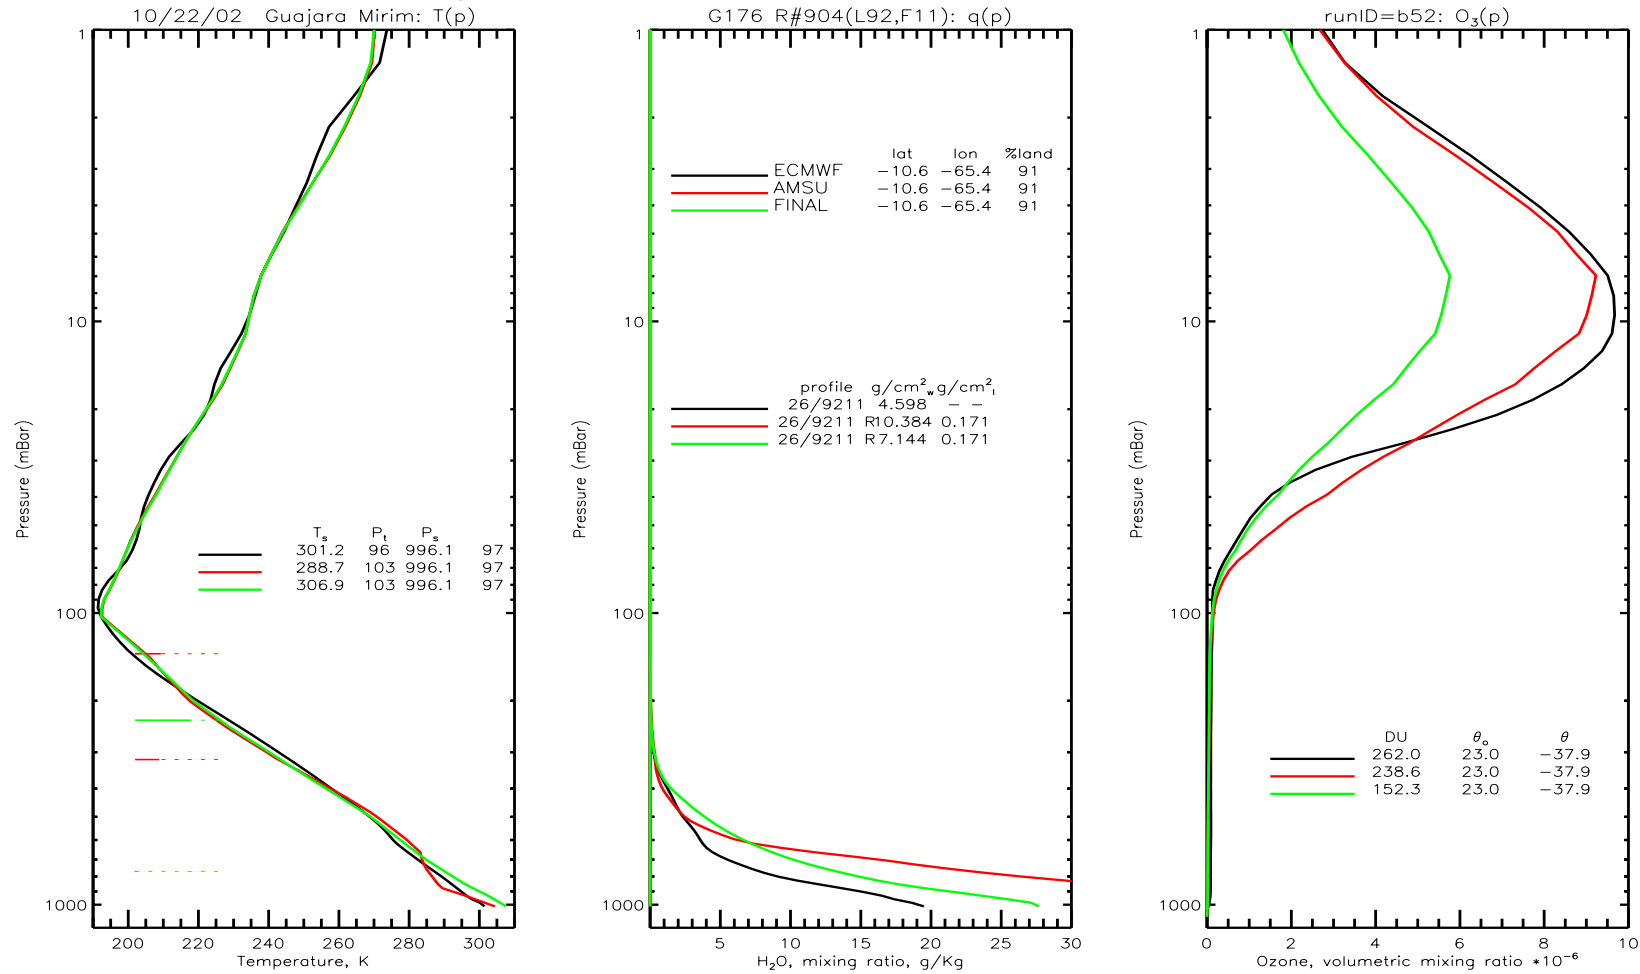

Baseline + removed microwave channels from all q(p) steps (including MIT).

# Oct. 22, 2002: 1:30 p.m.

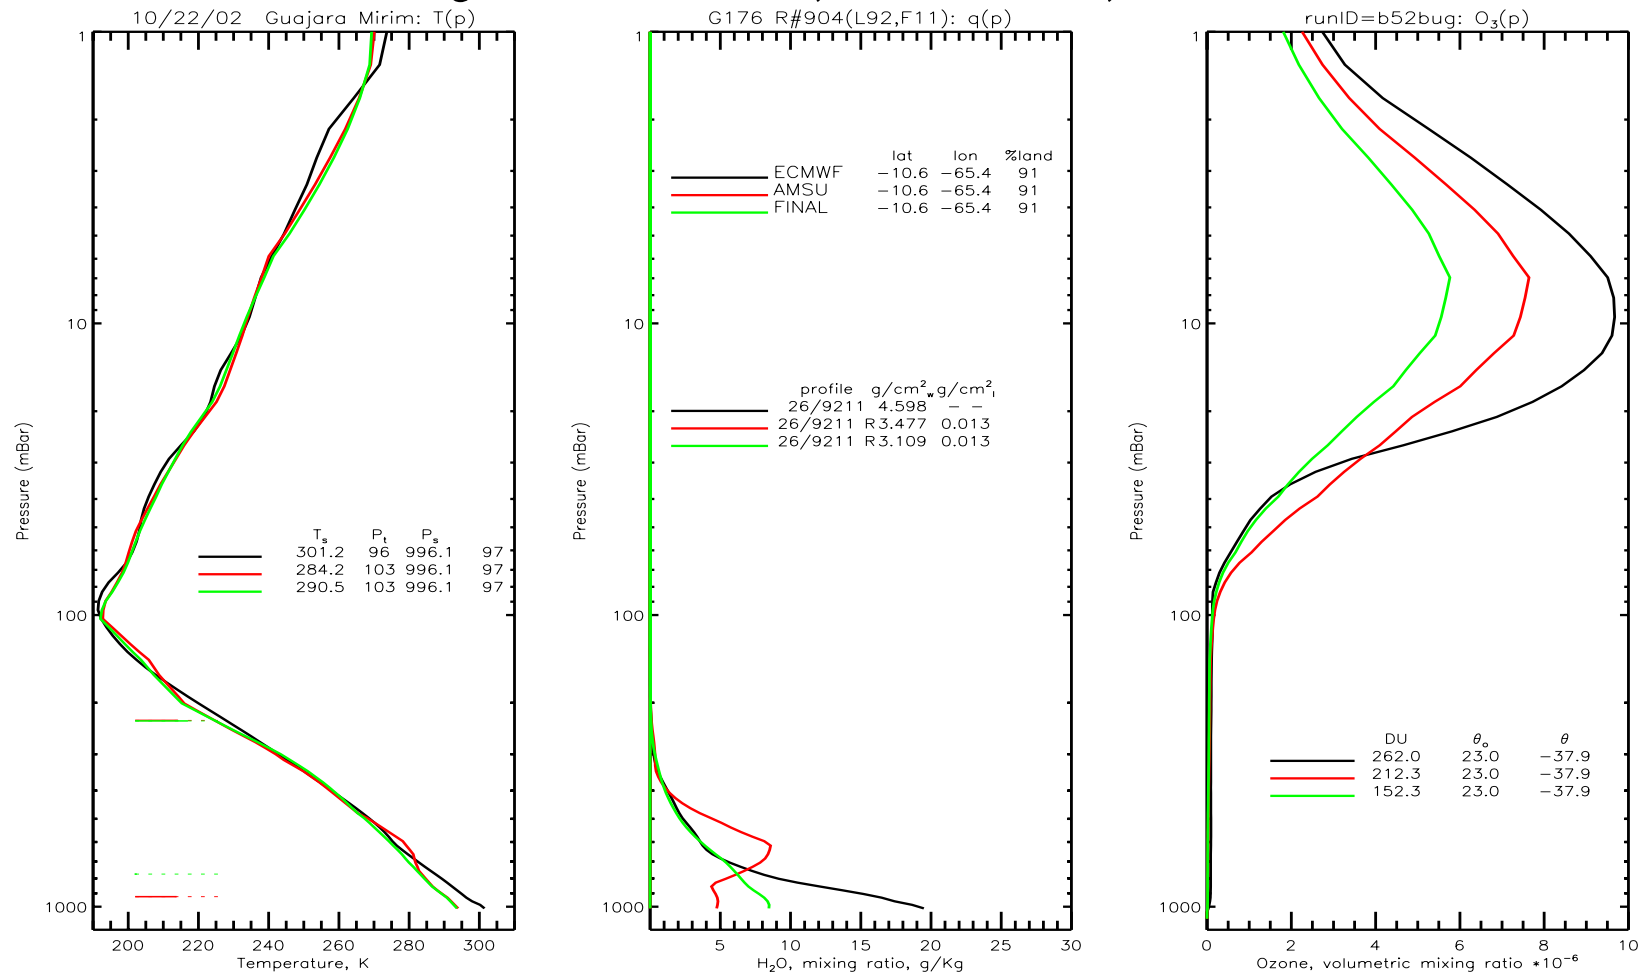

# Guajara Mirim, Oct. 22, 2003

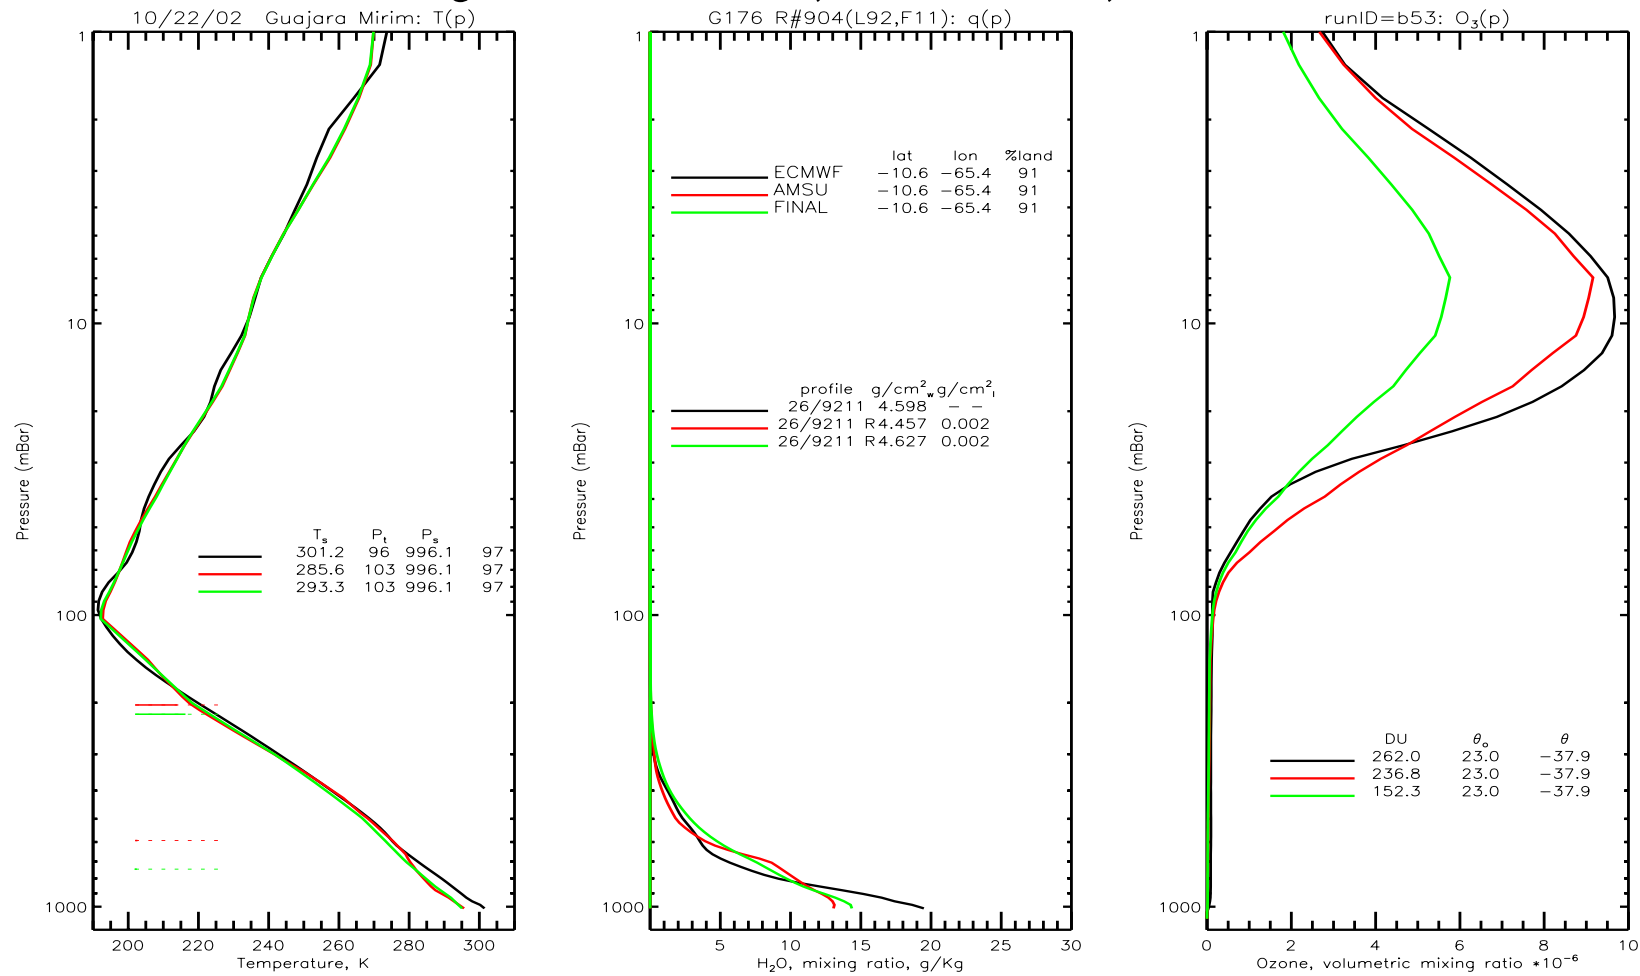

Baseline run (all known BUGS fixed) using  $T(n)=0$ ,  $E(n,n)$  is set as in Eqn. 1.3

# Guajara Mirim, Oct. 22, 2003

Baseline run w/ HSB T(n) BUGS re-installed. NOTE that L(p) is zero here. This emulates a “b30” system w/o TUNING

# Guajara Mirim, Oct. 22, 2003

Baseline + removed microwave channels from all q(p) steps (including MIT).

## Water Retrieval Conclusions

- “Correct” tuning causes MIT water vapor retrieval to exceed saturation and to have large liquid water. MIT retrieval does not reject these cases.
- ..or.. HSB tuning is a function of land/ocean or a function of moisture.
  - errors in forward model could be water dependent.
  - Earth shine on platform?
- In simulations we set a rejection criteria for Liquid Water  $\geq 0.3$  mm. This may be unnecessary.
- Infrared water retrieval is having a difficult time converging with HSB. The cloudier it gets, the more HSB is believed.
- I suggest we spend time with each and every case with coordinated observations during overpasses. There is a wealth of information to be gained from these difficult cases  $\Rightarrow$  need to work in an interactive manner with validation groups.
